

An email address such as "John.Smith@example.com" is made up of a local part ("John.Smith"), an "@" symbol, then a domain part ("example.com").

The domain name part of an email address may only consist of letters, digits, hyphens and dots. The local part, however, also allows a lot of different special characters. [Here](#) you can look at several examples of correct and incorrect email addresses.

Given a valid email address, find its domain part.

Example

- For address = "prettyandsimple@example.com", the output should be
- findEmailDomain(address) = "example.com";
- For address = "<>[:.,;@\"!#\$%&*+~/=?^_{}|~.a\"@example.org", the output should be
- findEmailDomain(address) = "example.org".

Input/Output

- **[execution time limit] 4 seconds (py)**
-
-
- **[input] string address**
- *Guaranteed constraints:*
- $10 \leq \text{address.length} \leq 50$.
-
-
- **[output] string**
